Abstract

Aims

Inflammatory cytokines play a critical role in the progression of calcific aortic valve disease (CAVD), for which there is currently no pharmacological treatment. The aim of this study was to test the hypothesis that interleukin-8 (IL-8), known to be involved in arterial calcification, also promotes aortic valve calcification (AVC) and to evaluate whether pharmacologically blocking the IL-8 receptor, CXC motif chemokine receptor 2 (CXCR2), could be effective in preventing AVC progression.

Abstract

Within the cardiovascular system, the protein vasorin (Vasn) is predominantly expressed by vascular smooth muscle cells (VSMCs) in the coronary arteries and the aorta. *Vasn* knockout ($Vasn^{-/-}$) mice die within 3 weeks of birth. In the present study, we investigated the role of vascular Vasn expression on vascular function. We used inducible *Vasn* knockout mice ($Vasn^{CRE\text{-}ERT\ KO}$ and $Vasn^{SMMHC\text{-}CRE\text{-}ERT2\ KO}$, in which respectively all cells or SMCs only are targeted) to analyze the consequences of total or selective Vasn loss on vascular function. Furthermore, in vivo effects were investigated in vitro using human VSMCs. The death of $Vasn^{CRE\text{-}ERT\ KO}$ mice 21 days after tamoxifen injection was concomitant with decreases in blood pressure, angiotensin II levels, and vessel contractibility to phenylephrine. The $Vasn^{SMMHC\text{-}CRE\text{-}ERT2\ KO}$ mice displayed concomitant changes in vessel contractibility in response to phenylephrine and angiotensin II levels. In vitro, *VASN* deficiency was associated with a shift toward the SMC contractile phenotype, an increase in basal intracellular Ca^{2+} levels, and a decrease in the SMCs' ability to generate a calcium signal in response to carbachol or phenylephrine. Additionally, impaired endothelium-dependent relaxation (due to changes in nitric oxide signaling) was observed in all *Vasn* knockout mice models. Our present findings highlight the role played by Vasn SMC expression in the maintenance of vascular functions. The mechanistic experiments suggested that these effects are mediated by SMC phenotype switching and changes in intracellular calcium homeostasis, angiotensin II levels, and NO signaling.

In chronic kidney disease (CKD), calcium-sensing receptor (CaSR) expression and function have been extensively studied in parathyroid tissue and vascular tissues. To examine whether similar changes occurred in other tissues, we measured total and surface CaSR expression in monocytes of patients with various stages of CKD and healthy volunteers respectively in cross-sectional studies. We further explored *in vitro* the impact of uremic serum on CaSR expression in monocytes (U937 and THP-1 cell lines), and whether human peripheral blood mononuclear cells or U937 and THP-1 monocytes might modify vascular calcium deposition in rat carotid arteries *in vitro*. CKD was associated with a decrease in peripheral blood mononuclear cell CaSR expression both in total and at the monocyte surface alone (43% and 34%, respectively in CKD stages 4-5). This decrease was associated with a reduction in the ability of monocytes to inhibit vascular calcification *in vitro*. Pretreatment with the calcimimetic NPSR568 of peripheral blood mononuclear cells isolated from patients with CKD significantly improved monocyte capacity to reduce carotid calcification *in vitro*. The fewer peripheral blood mononuclear cells expressing cell surface CaSR, the more calcimimetic treatment enhanced the decrease of carotid calcium content. Thus, we demonstrate that monocyte CaSR expression is decreased in patients with CKD and provide *in vitro* evidence for a potential role of this decrease in the promotion of vascular calcification. Hence, targeting this alteration or following monocyte CaSR expression as an accessible marker might represent a promising therapeutic strategy in CKD-associated arterial calcification.

Abstract

Rationale & Objective

Adverse drug reactions (ADRs) are common in patients with chronic kidney disease (CKD). The impact of kidney function decline on serious ADR risk has been poorly investigated. We sought to comprehensively describe ADRs and assess the relationship between eGFR and serious ADR risk.

Abstract

Background

Speckle tracking strain echocardiography allows one to visualize the timing of maximum regional strain and quantifies left ventricular-mechanical dispersion (LV-MD). Whether LV-MD and LV-global longitudinal strain (LV-GLS) provide similar or complementary information in mortality risk stratification in patients with severe aortic stenosis (SAS) remains unknown.

Objectives

We hypothesized that LV mechanical dyssynchrony assessed by LV-MD is associated with an increased risk of mortality and provides additional prognostic information on top of LV-GLS in patients with SAS.

CENTRAL ILLUSTRATION: Prognostic Implications of Left Ventricular Mechanical Dispersion in Severe Aortic Stenosis, Preserved Left Ventricular Ejection and Without Severe Symptoms

Hébergé au sein du CURS (le Centre Universitaire de Recherche en Santé) de l'Université de Picardie Jules Verne, sur le site du CHU Amiens-Picardie, le laboratoire Mécanismes Physiopathologiques et Conséquences des Calcifications Cardiovasculaires travaille sur les calcifications vasculaires, leurs mécanismes physiopathologiques et leurs conséquences.

Projet de recherche :

1. **Les mécanismes moléculaires impliqués dans les processus de calcifications et les facteurs/marqueurs associés.**
2. **Les conséquences hémodynamiques et structurales des calcifications cardiovasculaires chez l'animal et chez l'homme.**
3. **Les stratégies thérapeutiques pour prévenir et traiter ces calcifications.**
